## Descolea maculata

Descolea maculata © Patrick Leonard

**Cap:** convex to umbonate; 45 mm diameter; rugulose, radially wrinkled; yellowish brown (5B6).

**Stipe:** cylindrical or slightly wider at the base;  $30 - 50 \times 5$ mm; glabrous, yellowish brown; finely fibrillose; with a prominent striate to pleated ring about half-way up the stipe.

Gills: deeply adnexed; yellowish brown; lamellulae present in one series.

Flesh: thin, brownish.

**Spore print:** ochraceous brown.

**Spores:** amygdaliform (bean shaped);  $12 \times 7 \mu m$ ; with low but distinct warts.

**Basidia:** clavate,  $30 - 40 \times 8 - 12 \mu m$ , four spored.

Pleurocystidia: absent.

Pileipellis: a cutis.

**Habitat:** found growing on well-rotted wood in wet sclerophyll forests in Queensland but only known from three collections. Reported more frequently from other habitats in Tasmania, Victoria and Western Australia.

**Notes:** the very prominent striate ring and ochraceous brown spores are the distinctive features of this genus. *D. recedens* is more frequently reported from Queensland but has a taller stipe and a dark brown cap which is not rugulose.

**Collections examined:** PL1140521, Tewantin National Park, Pat Leonard, 30 May 2021.
